In the Cooper and John model, e_i represents the action of the ith agent, and \overline{e} is the average action of all agents, which we take to be the action of all other agents. The payoff to agent i is $V(e_i, \overline{e})$, with first and second partial derivatives:

$$\begin{split} &V_{1}\left(e_{i},\overline{e}\right) \equiv \frac{\partial V}{\partial e_{i}},\\ &V_{2}\left(e_{i},\overline{e}\right) \equiv \frac{\partial V}{\partial \overline{e}},\\ &V_{11}\left(e_{i},\overline{e}\right) \equiv \frac{\partial V_{1}}{\partial e_{i}} = \frac{\partial^{2} V}{\partial e_{i}^{2}},\\ &V_{12}\left(e_{i},\overline{e}\right) \equiv V_{21}\left(e_{i},\overline{e}\right) \equiv \frac{\partial V_{1}}{\partial \overline{e}} = \frac{\partial V_{2}}{\partial e_{i}} = \frac{\partial^{2} V}{\partial e_{i}\partial \overline{e}},\\ &V_{22}\left(e_{i},\overline{e}\right) \equiv \frac{\partial V_{2}}{\partial \overline{e}} = \frac{\partial^{2} V}{\partial \overline{e}^{2}}. \end{split}$$

Explain each of the following interpretations:

- 1. The marginal benefit of the action to agent i is V_1 .
- 2. Others' actions have *positive spillovers* on agent *i* if $V_2 > 0$.
- 3. Others' actions have *negative spillovers* on agent i if $V_2 < 0$.
- 4. Agent *i*'s action exhibits *strategic independence* if $V_{12} = 0$.
- 5. The action exhibits *strategic complementarity* if $V_{12} > 0$.
- 6. The action exhibits *strategic substitutability* if $V_{12} < 0$.
