## 1 Random Processes

$1^{\circ}$ Let $(\Omega, \mathcal{F}, P)$ be a probability space. By definition, $\Omega$ is a set, $\mathcal{F}$ is a $\sigma$-algebra of subsets of $\Omega$, and $P$ is a normalized finite nonnegative measure on $\mathcal{F}$. Let $L^{2}(\Omega)$ be the real hilbert space comprised of the square integrable real-valued measurable functions defined on $\Omega$. We will employ the following notations:

$$
\begin{equation*}
[F, G]:=\int_{\Omega} F(\omega) G(\omega) P(d \omega) \quad\left(F \in L^{2}(\Omega), G \in L^{2}(\Omega)\right) \tag{1}
\end{equation*}
$$

and:

$$
\begin{equation*}
[H, 1]=\int_{\Omega} H(\omega) P(d \omega) \quad\left(H \in L^{2}(\Omega)\right) \tag{2}
\end{equation*}
$$

For any functions $F$ and $G$ in $L^{2}(\Omega)$, one regards $F$ and $G$ as indistinguishable iff:

$$
\begin{equation*}
[F-G, F-G]=0 \tag{3}
\end{equation*}
$$

$2^{\circ}$ Let $J$ be the interval in $\mathbf{R}$ comprised of the nonnegative real numbers. Let $\lambda$ be lebesgue measure on the $\sigma$-algebra of borel subsets of $J$. By a realvalued random process on $J$, one means a measurable mapping $X$ carrying the product space $J \times \Omega$ to $\mathbf{R}$. For such a mapping, we will employ the following notation:

$$
\begin{equation*}
X(s)(\omega)=X_{s}(\omega)=X(s, \omega)=X_{\omega}(s)=X(\omega)(s) \quad(s \in J, \omega \in \Omega) \tag{4}
\end{equation*}
$$

We will require that:

$$
\begin{equation*}
X_{s} \in L^{2}(\Omega) \quad(0 \leq s) \tag{5}
\end{equation*}
$$

In effect, then, one may regard the random process $X$ as a mapping carrying $J$ to $L^{2}(\Omega)$ :

$$
J \xrightarrow{X} L^{2}(\Omega)
$$

jointly measurable in $s$ and $\omega$. One says that $X$ is continuous in the mean iff, as a mapping carrying $J$ to $L^{2}(\Omega), X$ is continuous. One says that $X$ has continuous trajectories iff, for each $\omega$ in $\Omega, X_{\omega}$ is continuous (as a real-valued function defined on $J$ ). In this case, one may regard $X$ as a mapping carrying $\Omega$ to $C(J)$ :

$$
\Omega \xrightarrow{X} C(J)
$$

jointly measurable in $s$ and $\omega$. By $C(J)$, one denotes the set comprised of all continuous real-valued functions defined on $J$.
$3^{\circ}$ Let $B$ be a real-valued random process on $J$ which defines a Brownian motion, with start state 0 :

$$
\begin{equation*}
B_{0}=0 \tag{6}
\end{equation*}
$$

The various basic properties of $B$ will emerge in due course. For each $r$ in $J$, let $\mathcal{E}_{r}$ be the $\sigma$-subalgebra of $\mathcal{F}$ comprised of all sets of the form:

$$
B_{r}^{-1}(A)
$$

where $A$ is any borel subset of $\mathbf{R}$. However, with regard to our subsequent description of the Ito Integral, let us take $\mathcal{E}_{0}$ to be the $\sigma$-subalgebra of $\mathcal{F}$ comprised of all sets $N$ in $\mathcal{F}$ for which either $P(N)=0$ or $P(N)=1$. In turn, let $\mathcal{F}_{s}$ be the $\sigma$-subalgebra of $\mathcal{F}$ generated by the union of the various $\sigma$-subalgebras $\mathcal{E}_{r}$, where $0 \leq r \leq s$ :

$$
\begin{equation*}
\mathcal{F}_{s}:=\overline{\bigcup_{0 \leq r \leq s} \mathcal{E}_{r}} \quad(0 \leq s) \tag{7}
\end{equation*}
$$

Clearly:

$$
\begin{equation*}
\mathcal{F}_{s} \subseteq \mathcal{F}_{t} \quad(0 \leq s<t) \tag{8}
\end{equation*}
$$

We will assume that the $\sigma$-subalgebra of $\mathcal{F}$ generated by the union of the various $\sigma$-subalgebras $\mathcal{F}_{s}$ is $\mathcal{F}$ itself:

$$
\begin{equation*}
\mathcal{F}=\overline{\bigcup_{0 \leq s} \mathcal{F}_{s}} \tag{9}
\end{equation*}
$$

We obtain a filtration of $\mathcal{F}$ :

$$
\begin{equation*}
\mathcal{F}_{s} \uparrow \mathcal{F} \tag{10}
\end{equation*}
$$

It may happen that:

$$
\begin{equation*}
\mathcal{F}_{t}=\overline{\bigcup_{0 \leq s<t} \mathcal{F}_{s}} \quad(0<t) \tag{11}
\end{equation*}
$$

or that:

$$
\begin{equation*}
\mathcal{F}_{s}=\bigcap_{s<t} \mathcal{F}_{t} \quad(0 \leq s) \tag{12}
\end{equation*}
$$

In the former case, one says that the filtration of $\mathcal{F}$ is left continuous; in the latter case, right continuous. In general, neither condition holds. However, Brownian motion has continuous trajectories, so both conditions hold.
$4^{\circ}$ For each $s$ in $J$, let $L_{s}^{2}(\Omega)$ be the closed linear subspace of $L^{2}(\Omega)$ comprised of all functions in $L^{2}(\Omega)$ which are measurable with respect to $\mathcal{F}_{s}$. Clearly:

$$
\begin{equation*}
L_{s}^{2}(\Omega) \subseteq L_{t}^{2}(\Omega) \quad(0 \leq s<t) \tag{13}
\end{equation*}
$$

Relation (9) entails that the closure of (the linear span of) the union of the various closed linear subspaces $L_{s}^{2}(\Omega)$ is $L^{2}(\Omega)$ itself. We obtain a filtration of $L^{2}(\Omega)$ :

$$
\begin{equation*}
L_{s}^{2}(\Omega) \uparrow L^{2}(\Omega) \tag{14}
\end{equation*}
$$

$5^{\circ}$ For each $s$ in $J$, let $\Pi_{s}$ be the orthogonal projection operator carrying $L^{2}(\Omega)$ to $L_{s}^{2}(\Omega)$. For each function $H$ in $L^{2}(\Omega), \Pi_{s}(H)$ is the conditional expectation of $H$ with respect to $\mathcal{F}_{s}$ :

$$
\begin{aligned}
\int_{A} \Pi_{s}(H)(\omega) P(d \omega) & =\left[\Pi_{s}(H), 1_{A}\right] \\
& =\left[H, \Pi_{s}\left(1_{A}\right)\right] \quad\left(A \in \mathcal{F}_{s}\right) \\
& =\left[H, 1_{A}\right] \\
& =\int_{A} H(\omega) P(d \omega)
\end{aligned}
$$

$6^{\circ}$ One refers to a random process $X$ as a martingale with respect to the given filtration of $\mathcal{F}$ iff:

$$
\begin{equation*}
\Pi_{r}\left(X_{s}\right)=X_{r} \quad(0 \leq r<s) \tag{15}
\end{equation*}
$$

It follows that:

$$
\begin{equation*}
\left[X_{s}, 1\right]=\left[X_{0}, 1\right] \quad(s \in J) \tag{16}
\end{equation*}
$$

so one may say that the martingale $X$ has mean $m:=\left[X_{0}, 1\right]$. Moreover:

$$
\begin{equation*}
\left(X_{s}-X_{r}\right) \perp L_{r}^{2}(\Omega) \quad(0 \leq r<s) \tag{17}
\end{equation*}
$$

$7^{\circ}$ By definition, $B$ is a martingale (having mean 0 ) with respect to the given filtration of $\mathcal{F}$, so:

$$
\begin{equation*}
\Pi_{r}\left(B_{s}\right)=B_{r} \quad(0 \leq r<s) \tag{18}
\end{equation*}
$$

and:

$$
\begin{equation*}
\left(B_{s}-B_{r}\right) \perp L_{r}^{2}(\Omega) \quad(0 \leq r<s) \tag{19}
\end{equation*}
$$

By definition:

$$
\begin{equation*}
\left[B_{s}-B_{r}, B_{s}-B_{r}\right]=(s-r) \quad(0 \leq r<s) \tag{20}
\end{equation*}
$$

This relation entails that $B$ is (uniformly) continuous in the mean. Moreover:

$$
\begin{align*}
{\left[H \left(B_{s}\right.\right.} & \left.\left.-B_{r}\right), H\left(B_{s}-B_{r}\right)\right] \\
& =\left[H^{2}\left(B_{s}-B_{r}\right)^{2}, 1\right] \\
& =\left[H^{2}, 1\right]\left[\left(B_{s}-B_{r}\right)^{2}, 1\right]  \tag{21}\\
& =[H, H](s-r)
\end{align*}
$$

because, by definition, $H^{2}$ and $\left(B_{s}-B_{r}\right)^{2}$ are independent. By $L_{r}^{\infty}(\Omega)$, one denotes the real algebra of real-valued functions $H$ defined on $\Omega$, measurable with respect to $\mathcal{F}_{r}$, and bounded (modulo $P$ ).

## 2 The Ito Integral

$8^{\circ}$ Let $t^{\prime}$ and $t^{\prime \prime}$ be any real numbers for which $0 \leq t^{\prime}<t^{\prime \prime}$. Let $\Sigma:=\left[t^{\prime}, t^{\prime \prime}\right]$. Let $\mathcal{W}_{\Sigma}$ be the real linear space comprised of all measurable mappings $X$ carrying the product space $\Sigma \times \Omega$ to $\mathbf{R}$, which meet the requirements that:

$$
\begin{equation*}
X_{s} \in L_{s}^{2}(\Omega) \quad\left(t^{\prime} \leq s \leq t^{\prime \prime}\right) \tag{22}
\end{equation*}
$$

and:

$$
\begin{equation*}
\int_{\Sigma}\left[X_{s}, X_{s}\right] \lambda(d s)<\infty \tag{23}
\end{equation*}
$$

Let $\mathcal{W}_{\Sigma}$ be supplied with the following inner product:

$$
\begin{equation*}
[X, Y]_{\Sigma}:=\int_{\Sigma}\left[X_{s}, Y_{s}\right] \lambda(d s) \quad\left(X \in \mathcal{W}_{\Sigma}, \quad Y \in \mathcal{W}_{\Sigma}\right) \tag{24}
\end{equation*}
$$

For any mappings $X$ and $Y$ in $\mathcal{W}_{\Sigma}$, one regards $X$ and $Y$ as indistinguishable iff:

$$
\begin{equation*}
[X-Y, X-Y]_{\Sigma}=0 \tag{25}
\end{equation*}
$$

By applying Fubini's Theorem, one can readily show that $X$ and $Y$ are indistinguishable iff there exists a set $N$ in $\mathcal{F}_{t^{\prime \prime}}$ such that $P(N)=0$ and such that, for each $\omega$ in $\Omega \backslash N$, there is a borel subset $M_{\omega}$ of $\Sigma$ such that $\lambda\left(M_{\omega}\right)=0$ and, for each $t$ in $\Sigma \backslash M_{\omega}, X_{\omega}(t)=Y_{\omega}(t)$. Now one may define the real linear mapping $I_{\Sigma}$ carrying $\mathcal{W}_{\Sigma}$ to $L_{t^{\prime \prime}}^{2}(\Omega)$ as follows. For mappings in $\mathcal{W}_{\Sigma}$ of the form:

$$
\begin{equation*}
H 1_{[r, s)} \quad\left(t^{\prime} \leq r<s \leq t^{\prime \prime}, \quad H \in L_{r}^{\infty}(\Omega)\right) \tag{26}
\end{equation*}
$$

one defines:

$$
\begin{equation*}
I_{\Sigma}\left(H 1_{[r, s)}\right):=H\left(B_{s}-B_{r}\right) \tag{27}
\end{equation*}
$$

One applies relation (21) to show that, on the linear span $\mathcal{W}_{\Sigma}^{0}$ of mappings of the foregoing form, $I_{\Sigma}$ preserves inner products; and one applies elementary arguments to show that $\mathcal{W}_{\Sigma}^{0}$ is dense in $\mathcal{W}_{\Sigma}$. One completes the definition of $I_{\Sigma}$ by passing to limit in the mean, obtaining the following fundamental relation:

$$
\begin{equation*}
\left[I_{\Sigma}(X), I_{\Sigma}(Y)\right]=[X, Y]_{\Sigma} \quad\left(X \in \mathcal{W}_{\Sigma}, Y \in \mathcal{W}_{\Sigma}\right) \tag{28}
\end{equation*}
$$

One refers to this relation as Ito's Relation of Isometry. It entails that $I_{\Sigma}$ is injective modulo the relation of indistinguishability on $\mathcal{W}_{\Sigma}$.
$9^{\circ}$ We will employ the following notation for the Ito Integral:

$$
\begin{equation*}
I_{\Sigma}(X)(\omega)=\int_{\Sigma} X(s, \omega) B(d s, \omega) \quad\left(X \in \mathcal{W}_{\Sigma}\right) \tag{29}
\end{equation*}
$$

where:

$$
\Sigma:=\left[t^{\prime}, t^{\prime \prime}\right]
$$

$10^{\circ}$ Now let $\mathcal{W}$ be the real linear space comprised of all real-valued random processes $X$ on $J$ which meet the requirements:

$$
\begin{equation*}
X_{s} \in L_{s}^{2}(\Omega) \quad(0 \leq s) \tag{30}
\end{equation*}
$$

and:

$$
\begin{equation*}
\int_{[0, t]}\left[X_{s}, X_{s}\right] \lambda(d s)<\infty \quad(0 \leq t) \tag{31}
\end{equation*}
$$

Let $\mathcal{W}$ be supplied with the following (pseudo-) inner products:

$$
\begin{equation*}
[X, Y]_{t}:=\int_{[0, t]}\left[X_{s}, Y_{s}\right] \lambda(d s) \quad(0 \leq t, X \in \mathcal{W}, Y \in \mathcal{W}) \tag{32}
\end{equation*}
$$

For any random processes $X$ and $Y$ in $\mathcal{W}$, one regards $X$ and $Y$ as indistinguishable iff:

$$
\begin{equation*}
[X-Y, X-Y]_{t}=0 \quad(0 \leq t) \tag{33}
\end{equation*}
$$

By applying Fubini's Theorem, one can readily show that $X$ and $Y$ are indistinguishable iff there exists a set $N$ in $\mathcal{F}$ such that $P(N)=0$ and such that, for each $\omega$ in $\Omega \backslash N$, there is a borel subset $M_{\omega}$ of $J$ such that $\lambda\left(M_{\omega}\right)=0$ and, for each $t$ in $J \backslash M_{\omega}, X_{\omega}(t)=Y_{\omega}(t)$.
$11^{\circ}$ Assembling the foregoing terms, we may describe the Ito Integral $I$ as the linear mapping carrying $\mathcal{W}$ to $\mathcal{W}$, defined and uniquely characterized by the conditions that:

$$
I\left(H 1_{[r, s)}\right)_{t}:=\left\{\begin{array}{ll}
0 & \text { if } 0 \leq t<r  \tag{34}\\
H\left(B_{t}-B_{r}\right) & \text { if } r \leq t<s \\
H\left(B_{s}-B_{r}\right) & \text { if } s \leq t
\end{array} \quad\left(0 \leq r<s, H \in L_{r}^{\infty}(\Omega)\right)\right.
$$

and:

$$
\begin{equation*}
\left[I(X)_{t}, I(Y)_{t}\right]=[X, Y]_{t} \quad(0 \leq t, X \in \mathcal{W}, Y \in \mathcal{W}) \tag{35}
\end{equation*}
$$

One presumes to define the Ito Integral $I$ as follows:

$$
\begin{equation*}
\left.I(X)_{t}:=I_{t}\left(X \downarrow \mathcal{W}_{t}\right) \quad(0 \leq t, \quad X \in \mathcal{W})\right) \tag{36}
\end{equation*}
$$

where:

$$
\begin{equation*}
\mathcal{W}_{t}:=\mathcal{W}_{[0, t]} \quad \text { and } \quad I_{t}:=I_{[0, t]} \tag{37}
\end{equation*}
$$

Clearly, $I(X)$ is a mapping carrying $J \times \Omega$ to $\mathbf{R}$ and it meets requirements (30) and (31). However, it may not be jointly measurable in $t$ and $\omega$. Nevertheless, one can show that $I(X)$ is a martingale (the definition of which does not require that $I(X)$ be jointly measurable in $t$ and $\omega$ ). One may then apply Doob's Theorem to "adjust" $I(X)$ so that it has continuous trajectories. For each $t$ in $J$, the old $I(X)_{t}$ and the new $I(X)_{t}$ are indistinguishable in $L^{2}(\Omega)$.

At this point, one should recall our specification of $\mathcal{E}_{0}$. (See Article $3^{\circ}$.) By this specification, it is plain that the new $I(X)_{t}$ must lie in $L_{t}^{2}(\Omega)$.
$12^{\circ}$ One can readily show that, for any mapping $X$ carrying $J \times \Omega$ to $\mathbf{R}$, if, for each $t$ in $J, X_{t}$ is measurable in $\omega$, and if, for each $\omega$ in $\Omega, X_{\omega}$ is continuous in $t$, then $X$ is jointly measurable in $t$ and $\omega$. It follows that the new $I(X)$ is jointly measurable in $t$ and $\omega$.
$13^{\circ}$ In this context, one should note that, for any random processes $X$ and $Y$ in $\mathcal{W}$, if $X$ and $Y$ have continuous trajectories then $X$ and $Y$ are indistinguishable iff there exists a set $N$ in $\mathcal{F}$ such that $P(N)=0$ and such that, for each $\omega$ in $\Omega \backslash N, X_{\omega}=Y_{\omega}$. Hence, modulo $P$, one can specify $I(X)$ precisely as a mapping carrying $J \times \Omega$ to $\mathbf{R}$.
$14^{\circ}$ The range of $I$ proves to be the real linear subspace of $\mathcal{W}$ comprised of all martingales which have mean 0 . This result is the Martingale Representation Theorem.
$15^{\circ}$ We will employ the following notation:

$$
\begin{equation*}
I_{t}(X)(\omega)=\int_{[0, t]} X(s, \omega) B(d s, \omega) \quad(0 \leq t, X \in \mathcal{W}) \tag{38}
\end{equation*}
$$

The range of $I_{t}$ proves to be the closed linear subspace of $L_{t}^{2}(\Omega)$ comprised of the functions $H$ for which $[H, 1]=0$. One refers to this fact as Ito's Representation Theorem.

## 3 Ito Processes

$16^{\circ}$ Let $U$ and $V$ be any random processes in $\mathcal{W}$. Let $X_{0}$ be any function in $L_{0}^{2}(\Omega)$. Such a function must in fact be constant modulo $P$. In terms of $U$, $V$, and $X_{0}$, one defines the random process $X$ in $\mathcal{W}$ as follows:

$$
\begin{equation*}
X(t, \omega):=X_{0}(\omega)+\int_{[0, t]} U(s, \omega) d s+\int_{[0, t]} V(s, \omega) B(d s, \omega) \tag{39}
\end{equation*}
$$

where $(t, \omega)$ is any ordered pair in $J \times \Omega$. In the foregoing relation, the second integral is Ito's integral $I_{t}$. Of course, one must verify that the first integral defines a random process in $\mathcal{W}$. One refers to $X$ as the Ito Process defined by $U, V$, and $X_{0}$.
$17^{\circ}$ For clarity, let us note that relation (39) (and all such relations to follow) must be interpreted modulo $\lambda \times P$. However, for each $\omega$ in $\Omega$, the first integral
in relation (39) is necessarily continous in $t$. By design of the Ito Integral, the second integral is also continuous in $t$. Hence, one may (implicitly) augment relation (39) by requiring that the random process $X$ have continuous trajectories. Therefore, modulo $P$, one can specify $X$ precisely as a mapping carrying $J \times \Omega$ to $\mathbf{R}$. (See Article $13^{\circ}$.)
$18^{\circ}$ Now let $\mathcal{M}$ be the family comprised of all real-valued functions $L$ defined and continuous on $J \times \mathbf{R}$, which meet the requirement that, for each $\tau$ in $J$, there is a nonnegative real number $\beta$ such that:

$$
\begin{equation*}
|L(t, x)-L(t, y)| \leq \beta|x-y| \quad(0 \leq t \leq \tau, x \in \mathbf{R}, y \in \mathbf{R}) \tag{40}
\end{equation*}
$$

It follows that:

$$
\begin{equation*}
\mid L(t, x \mid \leq \gamma(1+|x|) \quad(0 \leq t \leq \tau, x \in \mathbf{R}) \tag{41}
\end{equation*}
$$

where:

$$
\gamma:=\beta \vee \sup _{0 \leq t \leq \tau}|L(t, 0)|
$$

Let $L$ be any function in $\mathcal{M}$. For any random process $X$ in $\mathcal{W}$, one may form the mapping $\bar{X}$ carrying $J \times \Omega$ to $\mathbf{R}$ as follows:

$$
\begin{equation*}
\bar{X}(t, \omega):=L(t, X(t, \omega)) \quad((t, \omega) \in J \times \Omega) \tag{42}
\end{equation*}
$$

One can readily show that $\bar{X}$ is a random process in $\mathcal{W}$. To this end, one needs only requirement (41).

## 4 Stochastic Differential Equations

$19^{\circ}$ Let $X_{0}$ be any function in $L_{0}^{2}(\Omega)$ and let $K$ and $L$ be real-valued functions in $\mathcal{M}$. For each random process $X$ in $\mathcal{W}$, we may form the random process $Y$ in $\mathcal{W}$ as follows:
(43) $Y(t, \omega):=X_{0}(\omega)+\int_{[0, t]} K(s, X(s, \omega)) d s+\int_{[0, t]} L(s, X(s, \omega)) B(d s, \omega)$
where $(t, \omega)$ is any ordered pair in $J \times \Omega$. In this way, we obtain a mapping $\mathbf{T}$ carrying $\mathcal{W}$ to itself:

$$
\mathbf{T}(X):=Y \quad(X \in \mathcal{W})
$$

We plan to show that (in a certain sense) $\mathbf{T}$ is a contraction mapping on $\mathcal{W}$ and that, as a result, it admits a unique fixed "point" $Z$ :

$$
\begin{equation*}
Z(t, \omega):=X_{0}(\omega)+\int_{[0, t]} K(s, Z(s, \omega)) d s+\int_{[0, t]} L(s, Z(s, \omega)) B(d s, \omega) \tag{44}
\end{equation*}
$$

where $(t, \omega)$ is any ordered pair in $J \times \Omega$. One interprets this random process $Z$ as the solution of the stochastic differential equation:

$$
\begin{equation*}
\frac{d Z}{d t}(t, \omega)=K(t, Z(t, \omega))+L(t, Z(t, \omega)) W(t, \omega) \quad((t, \omega) \in J \times \Omega) \tag{45}
\end{equation*}
$$

uniquely determined by the initial condition:

$$
\begin{equation*}
Z(0, \omega)=X_{0}(\omega) \quad(\omega \in \Omega) \tag{46}
\end{equation*}
$$

By $W$, one denotes the fictitious random process called white noise. One imagines that:

$$
\begin{equation*}
B(d s, \omega)=W(s, \omega) d s \tag{47}
\end{equation*}
$$

$20^{\circ}$ Let us show that there is precisely one solution $Z$ to the integral form (44) of the stochastic differential equation (45). Let $\tau$ be any positive real number. Let $\beta$ be a nonnegative real number for which:

$$
\begin{equation*}
|K(t, x)-K(t, y)| \vee|L(t, x)-L(t, y)| \leq \beta|x-y| \tag{48}
\end{equation*}
$$

where $t$ is any real number for which $0 \leq t \leq \tau$ and where $x$ and $y$ are any real numbers. Let $t^{\prime}$ and $t^{\prime \prime}$ be any real numbers for which $0 \leq t^{\prime}<t^{\prime \prime} \leq \tau$ and let $\Sigma:=\left[t^{\prime}, t^{\prime \prime}\right]$. Let $X_{t^{\prime}}$ be any function in $L_{t^{\prime}}^{2}(\Omega)$. Let $\mathbf{T}$ be the mapping carrying $\mathcal{W}_{\Sigma}$ to itself, defined as follows:

$$
\mathbf{T}(X)(t, \omega):=X_{t^{\prime}}(\omega)+\int_{\left[t^{\prime}, t\right]} K(s, X(s, \omega)) d s+\int_{\left[t^{\prime}, t\right]} L(s, X(s, \omega)) B(d s, \omega)
$$

where $X$ is any mapping in $\mathcal{W}_{\Sigma}$ and where $(t, \omega)$ is any ordered pair in $\Sigma \times \Omega$. The second of the foregoing integrals is Ito's Integral $I_{\left[t^{\prime}, t\right]}$. We will prove that:

$$
\begin{align*}
& {\left[\mathbf{T}\left(X^{\prime}\right)-\mathbf{T}\left(X^{\prime \prime}\right), \mathbf{T}\left(X^{\prime}\right)-\mathbf{T}\left(X^{\prime \prime}\right)\right]_{\Sigma}} \\
& \quad \leq 2 \beta^{2}\left(1+\tau^{2}\right)\left(t^{\prime \prime}-t^{\prime}\right)\left[X^{\prime}-X^{\prime \prime}, X^{\prime}-X^{\prime \prime}\right]_{\Sigma} \tag{50}
\end{align*}
$$

where $X^{\prime}$ and $X^{\prime \prime}$ are any mappings in $\mathcal{W}_{\Sigma}$. Hence, if $t^{\prime \prime}-t^{\prime}$ is sufficiently small then $\mathbf{T}$ is a contraction mapping carrying $\mathcal{W}_{\Sigma}$ to itself.
$21^{\circ}$ Let us assume for the moment that we have proved relation (50). Let:

$$
0=t_{0}<t_{1}<t_{2}<\cdots<t_{k-1}<t_{k}=\tau
$$

be a partition of $[0, \tau]$ for which:

$$
2 \beta^{2}\left(1+\tau^{2}\right)\left(t_{j+1}-t_{j}\right)<1 \quad(0 \leq j<k)
$$

By repeated application of the Contraction Mapping Principle, we can design a mapping $Z_{\tau}$ in $\mathcal{W}_{\tau}$ such that:

$$
\begin{equation*}
Z_{\tau}(t, \omega):=X_{0}(\omega)+\int_{[0, t]} K\left(s, Z_{\tau}(s, \omega)\right) d s+\int_{[0, t]} L\left(s, Z_{\tau}(s, \omega)\right) B(d s, \omega) \tag{51}
\end{equation*}
$$

where $(t, \omega)$ is any ordered pair in $[0, \tau] \times \Omega$. Letting $\tau$ tend to $\infty$, we can obtain the random process $Z$ in $\mathcal{W}$ satisfying (and uniquely determined by) relation (44).
$22^{\circ}$ Let us prove relation (50). Let $X^{\prime}$ and $X^{\prime \prime}$ be any mappings in $\mathcal{W}_{\Sigma}$. Let us adopt the following notational compressions:

$$
\begin{aligned}
& F(s, \omega):=K\left(s, X^{\prime}(s, \omega)\right)-K\left(s, X^{\prime \prime}(s, \omega)\right) \quad((s, \omega) \in \Sigma \times \Omega) \\
& G(s, \omega):=L\left(s, X^{\prime}(s, \omega)\right)-L\left(s, X^{\prime \prime}(s, \omega)\right) \quad
\end{aligned}
$$

We have:

$$
\begin{aligned}
& {\left[\mathbf{T}\left(X^{\prime}\right)-\mathbf{T}\left(X^{\prime \prime}\right), \mathbf{T}\left(X^{\prime}\right)-\mathbf{T}\left(X^{\prime \prime}\right)\right]_{\Sigma}} \\
& \begin{aligned}
&= \int_{\Sigma} \int_{\Omega}\left|\int_{\left[t^{\prime}, t\right]} F(s, \omega) \lambda(d s)+\int_{\left[t^{\prime}, t\right]} G(s, \omega) B(d s, \omega)\right|^{2} P(d \omega) \lambda(d t) \\
& \leq 2 \int_{\Sigma}\left\{\int_{\Omega}\left|\int_{\left[t^{\prime}, t\right]} F(s, \omega) \lambda(d s)\right|^{2} P(d \omega)\right. \\
&\left.\quad+\int_{\Omega}\left|\int_{\left[t^{\prime}, t\right]} G(s, \omega) B(d s, \omega)\right|^{2} P(d \omega)\right\} \lambda(d t) \\
& \leq 2 \int_{\Sigma}\left\{\left(t-t^{\prime}\right)^{2} \int_{\Omega} \int_{\left[t^{\prime}, t\right]} F(s, \omega)^{2} \lambda(d s) P(d \omega)\right. \\

& \leq 2 \beta^{2}\left(1+\tau^{2}\right)\left[X^{\prime}-X^{\prime \prime}, X^{\prime}-X^{\prime \prime}\right]_{\Sigma} \int_{\Sigma} \lambda(d t) \\
&= 2 \beta^{2}\left(1+\tau^{2}\right)\left(t^{\prime \prime}-t^{\prime}\right)\left[X^{\prime}-X^{\prime \prime}, X^{\prime}-X^{\prime \prime}\right]_{\Sigma}
\end{aligned}
\end{aligned}
$$

which proves relation (50).
$23^{\circ}$ Let us emphasize that the random process $Z^{\prime}=Z$ which appears on the left side of relation (44) and the random processs $Z^{\prime \prime}=Z$ which appears (twice) on the right side of relation (44) are, though indistinguishable, not identically the same as mappings. However, with reference to Articles $11^{\circ}$, $12^{\circ}$, and $13^{\circ}$, we may arrange that $Z^{\prime}$ have continuous trajectories and we may infer that, modulo $P$, the random process $Z$ in $\mathcal{W}$ which satisfies relation (44) is uniquely determined as a mapping carrying $J \times \Omega$ to $\mathbf{R}$.
